Growth patterns of neonatal and older children with short bowel syndrome. The growth patterns of nine short bowel syndrome patients, aged 1-8 years, were studied and compared with data from a normal growth chart published by the World Health Organization. In addition to examining the growth of the children with short bowel syndrome, this study attempted to establish if there were early manifestations of stunting in this group of patients. The children had a mean age of 5.5 (range 1-8) years at the time of data collection. The mean residual small bowel length was 190.2 (range 0.5-288.2) cm and the mean age of all patients at the time of short bowel resection was 1.3 (range 0.5-5.5) years. The charts were compared with the standard growth chart of the World Health Organization. The growth patterns of the children with short bowel syndrome were similar to children of normal stature, except for the period after the age of 5 years. There was no correlation between the total number of complications that these children experienced and their height standard deviation score (SSS). In this study it is suggested that the pattern of growth of patients with short bowel syndrome may follow a similar pattern as that of normal children of similar age. It is concluded that the mild degree of malabsorption caused by short bowel syndrome does not appear to have an effect on the growth of these patients.

CLICK HERE A recently published study by Cornell University researchers has identified a large and growing subset of Americans who are striking it rich in the modern American economy. The study found that between 1992 and 2005, the share of Americans with annual incomes more than \$100,000 more than doubled, from 1 percent to 2.9 percent. What's more, these Americans now constitute by far the largest part of the growth in the distribution of income and, we can infer, are a large part of the growth in consumption. The study analyzed federal census data and asked how many people received \$100,000 or more last year. This included all income not received in taxes, which the researchers estimate to be \$1.2 trillion last year. It's important not to read too much into these numbers, since it's impossible to determine which Americans are in the upper echelons of the income distribution and which ones aren't. "In our study, we define high income as people in the 95th percentile of the income distribution," said the study's author, David Colander, "so this may or may not include people who are close to the median." But the size and composition of this segment of the population are critical and tell us something about the distribution of income. Census data are official, presumably accurate, numbers coming directly from the government itself. The numbers obviously understate the real impact of a growing upper income group, but the adjustment is easily done since it is close to zero. Census data is also a really good measure of how the economy is doing, since it covers a range of income groups. The raw data is available online at [The number of cases I checked ranged from 198,000 \(1982\) to 6,556,000 \(2005\)](#). (See
